Xylem - Wikipedia Introduction This article describes xylem structure primarily in relation to its function in long distance water transport. Our goal is to provide a brief update of the major findings in the field of xylem structure and function since M. Zimmermann published his excellent book in 1983 (Zimmermann 1983). In

Xylem formation begins when the actively dividing cells of growing root and shoot tips (apical meristems) give rise to primary xylem. In woody plants, secondary xylem constitutes the major part of a mature stem or root and is formed as the plant expands in girth and builds a ring of new xylem around the original primary xylem tissues. When this happens, the primary xylem cells die and lose their conducting function, forming a hard skeleton that serves only to support the plant.

The structure of xylem and phloem is also different. While xylem is made up of tracheids and vessels, phloem is made up of sieve tubes which have many holes for transporting nutrients. Xylem is star-shaped, while phloem is round and actually surrounds the xylem.

These observations have important implications for xylem development and bacterial migration through xylem. Vascular structure of the leaf. The diameter of xylem conduits decreased towards the margin in leaves of grape, similar to sunflower (Wang, 1985; Canny, 1993). At about 50–60 % of the leaf length, movement of paint particles and low-pressure air halted, indicating that the open conduits ended before the leaf margins.

Xylem is the specialised tissue of vascular plants that transports water and nutrients from the plant–soil interface to stems and leaves, and provides mechanical support and storage. The water-conducting function of xylem is one of the major distinguishing features of vascular plants.

Xylem is one of the two types of transport tissue in vascular plants, phloem being the other. The basic function of xylem is to transport water from roots to stems and leaves, but it also transports nutrients. The word "xylem" is derived from the Greek word ξύλον, meaning "wood"; the best-known xylem tissue is wood, though it is found throughout a plant. The term was introduced by Carl Nägeli in 1858.

Xylem structure. Secondary xylem tissue in red maple stem is diffuse porous. It consists of vessel members (Figs 1, 2), tracheids with round bordered pits, parenchyma, and long libriform fibres (observation of xylem macerate, data not shown). Large diameter tracheary elements can be identified as vessels, but the smaller diameter vessels and tracheids are not distinguishable in a cross-section and, therefore, they were all grouped into tracheary elements.

INTRODUCTION. Xylella fastidiosa (Xf) is a xylem-limited bacterium that lives as a harmless endophyte in most plants species, but various subspecies and strains of Xf are differentially pathogenic in several agriculturally important crops such as coffee, citrus and grapevine (Hopkins and Purcell, 2002).The bacterium is transmitted by xylem sap-feeding sharpshooter leafhoppers (Redak et al ...
